

Clarification on Interaction Conditions and Disclosure of AI Use

Participants will interact in **two types of conversation conditions** during the study:

1. **Human-Human Condition:** Participants communicate with another participant who is present at the lab at the same time, located in a separate room. In this condition, no AI chatbot is involved in the experiment.
2. **Human-AI Condition:** Participants communicate with an AI chatbot (ChatGPT).

Each participant will take part in both conditions, meaning that all participants will interact both with another human and with the AI chatbot at different points during the experiment. The conversational prompts are the same across both conditions, allowing for within-subject comparisons.

Therefore, each participant will interact in each prompt condition for 5 minutes with the other participant. This condition does not include any AI use. Furthermore, each participant will interact in each prompt condition for 5 minutes with the AI chatbot. This condition does include AI use, as the interaction partner is an AI chatbot.

The order of the conditions and prompts is randomized and cross-balanced. This randomization is identical for the two participants present in the lab at the same time. When the condition is "human-human," they interact with each other. When the condition is "human-AI," each participant independently interacts with the AI chatbot. There is no interaction with researchers during the chat tasks.

Participants are not informed before or during each chat whether they are communicating with a human or an AI. However, they are aware that both types of interactions will occur. After each interaction, at an intermediate screen between trials, they are asked to evaluate their experience of flow, social presence, and to indicate whether they believe they were interacting with a human or an AI. A full debriefing will be provided at the end of the study to inform participants about the nature of their conversation partners across the experiment.

Regarding data handling, we clarify that in the human-AI condition, chat messages are transmitted to and processed by a third-party service (OpenAI) as part of the chatbot interaction. Therefore, participants are made aware that some of their messages will necessarily be transmitted to a third party when interacting with the AI. The phrasing "might be" has been used because only half of the conversations involve an AI chatbot.
